## **Preliminaries**

#### Mathematical Problem

Given a function  $f \in \mathcal{C}$  where  $\mathcal{C}$  is some class of functions, how many weights, nodes, and layers does one need to approximate f with certain accuracy in some predefined metric?

#### A Neural Network Class to be considered

We first introduce the formal mathematical representation of the FNN model as follows:

- The network architecture (L, p) consists of a positive integer L called the number of hidden layers and a width vector  $p = (p_0, \dots, p_{L+1})$ .
- A neural network with network architecture (L, p) is any function of the form

$$f: \mathbb{R}^{P_0} \to \mathbb{R}^{P_{L+1}}, f(x) = W_L \sigma_{V_L} W_{L-1} \sigma_{V_{L-1}} \dots W_1 \sigma_{V_1} W_0 x,$$
 (1)

where  $W_i$  is a  $p_{i+1} \times p_i$  weight matrix and  $v_i \in \mathbb{R}^{p_i}$  is a shift vector.

 $\sigma$  denotes a ReLU activation function, where it is defined as  $\sigma(x) = \max(x, 0)$ .

#### A Neural Network Class to be considered

All parameter values in the network are bounded by one:

$$\mathcal{F}(\textit{L},\textit{p}) := \big\{\textit{f} \text{ of the form (1)}: \max_{j=0,\ldots,\textit{L}} \|\textit{W}_j\|_{\infty} \vee |\textit{v}_j|_{\infty} \leq 1 \big\},$$

Proof

where  $||W_i||_{\infty}$  denotes the maximum entry norm of  $W_i$ .

There are only a few non-zero/active network parameters:

$$\sum_{i=0}^{L} \|W_j\|_0 + |v_j|_0 \leq s.$$

where  $||W_i||_0$  denotes the number of non-zero entries of  $W_i$ .

Combining all the imposed assumptions, we are going to consider a neural network class whose architecture is constructed as follows:

$$\mathcal{F}(L, \rho, s, F) := \left\{ f(x) \in \mathcal{F}(L, \rho) : \sum_{i=0}^{L} \|W_j\|_0 + |v_j|_0 \le s, \|f\|_{\infty} \le F \right\}.$$

# Assumption on Regression function

- Hölder class with  $\beta$ -smoothness index is one of the most commonly studied function classes in literature.
- For  $\beta = n + \sigma$  where  $n \in \mathbb{N}_0$  and  $\sigma \in (0, 1]$ , a function has hölder smoothness index  $\beta$  if all partial derivatives up to order n exist and are bounded and the partial derivatives of order n are  $\sigma$ hölder.

Proof

The ball of  $\beta$ -hölder functions with radius K is then defined as

$$C_r^{\beta}(D,K) = \left\{ f : D \subset \mathbb{R}^r \to \mathbb{R} : \sum_{\alpha:|\alpha| \le n} \|\partial^{\alpha} f\|_{\infty} + \sum_{\alpha:|\alpha| = n} \sup_{\mathbf{x}, \mathbf{y} \in D} \frac{|\partial^{\alpha} f(\mathbf{x}) - \partial^{\alpha} f(\mathbf{y})|}{|\mathbf{x} - \mathbf{y}|_{\infty}^{\sigma}} \le K \right\}.$$

In Hieber (2020),  $D = [0, 1]^r$ . In Petersen and Voigtlaender (2018),  $D = \begin{bmatrix} -\frac{1}{2}, \frac{1}{2} \end{bmatrix}^r$  where r is an input dimension.

## **Theorem Statement**

#### Theorem 5 of Hieber 2020

For any function  $f \in C_r^{\beta}([0,1]^r, K)$  and any integers  $m \ge 1$  and  $N \ge (\beta + 1)^r \lor (K + 1)e^r$ , there exists a network

$$\tilde{f} \in \mathcal{F}(L, (r, 6(r + \lceil \beta \rceil)N, \dots, 6(r + \lceil \beta \rceil)N, 1), s, \infty)$$

with depth

$$L = 8 + (m+5)(1 + \lceil \log_2(r \vee \beta) \rceil)$$

and the number of parameters

$$s \leq 141(r+\beta+1)^{3+r}N(m+6),$$

such that

$$\left\|\tilde{f} - f\right\|_{L^{\infty}[0,1]^r} \le (2K+1)(1+r^2+\beta^2)6^r N 2^{-m} + K3^{\beta} N^{-\frac{\beta}{r}}.$$

# Key Ideas

# Key Ideas for proof of Theorem

Key ideas for approximating functions in  $C_r^{\beta}(D, K)$  with Neural Network are mainly two folded:

- Local Taylor Approximation: We split the input space into small hyper-cubes and construct a network that approximates a local Taylor expansion on each of these hyper-cubes.
- Approximation of multiplication operator: We need to build networks that for given input (x, y) approximately compute the product xy.

Proof

# **Local Taylor Approximation?**

- Discretize the input space  $[0,1]^r$  with a set of points  $D(M) := \{X_\ell = (\ell_j/M)_{j=1,2,\ldots,r}, \ell = (\ell_1,\ell_2,\ldots,\ell_r) \in \{0,1,2,\ldots,M\}^r\}$ . The cardinality of this set is  $(M+1)^r$ .
- Think of Taylor expansion of f(x) at one of the grid points,  $x_{\ell} \in D(M)$ , with up to degree n, which can be written as

$$P_{x_{\ell}}^{\beta}f(x) := \sum_{\alpha: |\alpha| \leq n} (\partial^{\alpha}f)(x_{\ell}) \frac{(x-x_{\ell})^{\alpha}}{\alpha!}.$$

■ For an arbitrary input  $x \in [0, 1]^r$ , Local Taylor approximation of  $f \in C_r^{\beta}([0, 1]^r, K)$  can be written as follows:

$$P^{\beta}f(x):=\sum_{x_{\ell}\in D(M)}P_{x_{\ell}}^{\beta}f(x)\prod_{j=1}^{r}\left(1-M|x_{j}-x_{j}^{\ell}|\right)_{+},$$

where  $x = \{x_1, x_2, \dots, x_r\}.$ 

Local Taylor Approximation

 $\forall x \in [0,1]^r$ , Local Taylor Approximation of f(x) is written as linear combination of  $2^r$  terms of  $P_{x_\ell}^{\beta} f(x)$ , for which  $x_\ell \in D(M)$ such that  $||x - x_{\ell}||_{\infty} \leq \frac{1}{M}$ .

Proof

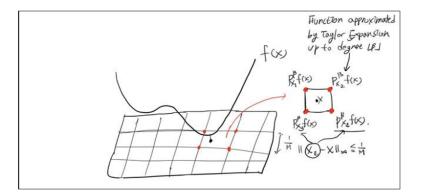

Figure 1: Visualization of intuition on Local Taylor Approximation when r = 2.

## Proof

## First Step

Preliminaries

First Step

- Neural Network  $\tilde{f}$  is not directly used to approximate  $f \in \mathcal{C}_r^{\beta}([0,1]^r,K)$ , instead it is used to approximate the approximated f through local Taylor expansion, where we denote it as  $P^{\beta}f(X)$ .
- For  $X \in [0,1]^r$ , the closeness between functions is measured in a  $L^{\infty}$  sense. Approximation error can be decomposed with the help of triangular inequality as follows:

$$\left\|\tilde{f}-f\right\|_{L^{\infty}[0,1]^r}\leq \underbrace{\left\|P^{\beta}f(X)-f(X)\right\|_{L^{\infty}[0,1]^r}}_{\textcircled{\tiny{1}}}+\underbrace{\left\|\tilde{f}-P^{\beta}f(X)\right\|_{L^{\infty}[0,1]^r}}_{\textcircled{\tiny{2}}}.$$

Controlling (2) will be the main focus, whereas a term (1) can be easily controlled trough the definition of Hölder class.

rem: for any  $\xi \in [0,1]$  and any  $a \in [0,1]^r$ ,

Preliminaries First Step

# Observe f(x) can be written as follows by Multivariate Taylor's Theo-

$$f(x) = \sum_{\alpha: |\alpha| \le n-1} \partial^{\alpha} f(a) \frac{(x-a)^{\alpha}}{\alpha!} + \sum_{\alpha: |\alpha| = n} \partial^{\alpha} f(a+\xi(x-a)) \frac{(x-a)^{\alpha}}{\alpha!}.$$

So for  $f \in \mathcal{C}_r^{\beta}([0,1]^r, K)$ ,

$$|f(x) - P_a^{\beta} f(x)| = \sum_{\alpha: |\alpha| = n} |\partial^{\alpha} f(a + \xi(x - a)) - \partial^{\alpha} f(a)| \frac{|(x - a)^{\alpha}|}{\alpha!}$$
  
$$\leq K|x - a|_{\infty}^{\beta}.$$

## Control on 1

It is interesting to observe a following fact

$$\sum_{x_{\ell} \in D(M)} \prod_{j=1}^r \left( 1 - M |x_j - x_j^{\ell}| \right)_+ = \prod_{j=1}^r \sum_{\ell=1}^M \left( 1 - M \left| x_j - \frac{\ell}{M} \right| \right)_+ = 1.$$

By using this relation, we can see

$$\begin{aligned} & \left\| P^{\beta}(x) - f(x) \right\|_{L^{\infty}[0,1]^{r}} \\ &= \left| \sum_{x_{\ell} \in D(M)} \left( \underbrace{P^{\beta}_{x_{\ell}} f(x) - f(x)}_{\leq K|x - x_{\ell}|_{\infty}^{\beta}} \right) \prod_{j=1}^{r} \left( 1 - M|x_{j} - x_{j}^{\ell}| \right)_{+} \right|_{\infty} \\ &\leq K M^{-\beta}. \end{aligned}$$

# **Second Step**

In order to control the term ②, of course, we first need to build a Neural network which can approximate  $P^{\beta}(X)$ . This step is involved with several sub-steps:

- For all  $x_{\ell} \in D(M)$  and for an arbitrary input  $x \in [0, 1]^r$ , we need to build a Neural Network which can approximate  $P_{x_{\ell}}^{\beta}(x)$ .

  Constructed Neural Network has output in  $\mathbb{R}^{(M+1)^r}$ .
- 2 For all  $x_{\ell} \in D(M)$  and for an arbitrary input  $x \in [0,1]^r$ , we need to build a Neural Network which can approximate  $\prod_{j=1}^r \left(\frac{1}{M} |x_j x_j^{\ell}|\right)_+.$  Constructed Neural Network has output in  $\mathbb{R}^{(M+1)^r}$  as well.

Second Step

# Involved Tools for approximating $P_{x_{\alpha}}^{\beta} f(x)$

Through a r-dimensional Binomial theorem, we can write  $P_{x_e}^{\beta}(x)$  as linear combination of monomials:

$$P_{x_\ell}^{eta}f(x):=\sum_{lpha:|lpha|\leq n}(\partial^lpha f)(x_\ell)rac{(x-x_\ell)^lpha}{lpha!}=\sum_{\gamma:|\gamma|\leq n}C_\gamma x^\gamma.$$

In order to construct a neural network which can approximate  $P_{x_a}^{\beta}f(x)$ for a  $x_{\ell}$ , we need following tools:

- Multiplication operator  $Mult_m(x, y)$  which can approximate the product of two input data x, y.
- Product operator  $Mult_m^r(x_1,\ldots,x_r)$  which can approximate  $\prod_{i=1}^r x_i$ for an input data  $x \in [0, 1]^r$ .
- **3** Monomial operator  $Mon_{m,\gamma}^r(x_1,\ldots,x_r)$  which can approximate all monomials with up to degree  $|\gamma| < n$ .

#### Lemma A.1.

In order to construct a neural network which can compute the product of two input data, we first need to have a ReLU neural network which can approximate x(1-x) for an  $x \in \mathbb{R}$ .

**(Lemma A.1.)** Let 
$$T^k : [0, 2^{2-2k}] \to [0, 2^k],$$

$$T^k(x) := T_+(x) - T_-^k(x) = (x/2)_+ - (x-2^{1-2k})_+,$$

and  $R^k : [0,1] \to [0,2^{-2k}]$ ,

$$R^k(x) := T^k \circ T^{k-1} \circ, \ldots, T^1.$$

Then, for any positive integer *m*,

$$\left| x(1-x) - \sum_{k=1}^{m} R^{k}(x) \right| \leq 2^{-m}.$$

Detailed proof using induction can be found in the paper.

#### Visual Illustration of Lemma A.1.

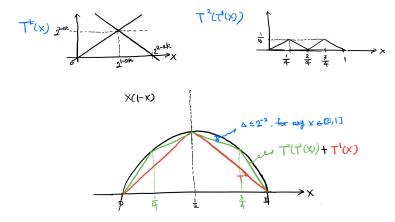

Figure 2: Intuition behind Lemma A.1. can be easily captured by visualization. The Lemma can be proved rigorously via proof by induction on *m*.

For given input x, y, we construct a network which returns approximately xy.

**(Lemma A.2.)** For any positive integer m, there exists a network  $Mult_m \in \mathcal{F}(m+4,(2,6,6,\ldots,6,1))$ , such that  $Mult_m(x,y) \in [0,1]$ ,

$$|Mult_m(x,y)-xy| \leq 2^{-m}, \quad \forall x,y \in [0,1],$$

and  $Mult_m(x,0) = Mult_m(0,y) = 0$ .

Let g(x) = x(1-x) and use a following polarization identity :

$$xy = \underbrace{\left(g\left(\frac{x-y+1}{2}\right) + \frac{x+y}{2}\right)}_{\text{(1)}} - \underbrace{\left(g\left(\frac{x+y}{2}\right) + \frac{1}{4}\right)}_{\text{(2)}}$$

Our goal is to construct two neural networks which can approximate (1) and (2).

Second Step

# Realization of $Mult_m(x, y)$

We can show that there is a network  $N_m$  with m hidden layers and width vector  $(3, 3, 3, \ldots, 3, 1)$  that computes the function  $(T_+(u), T_-^1(u), h(u)) \rightarrow \sum_{k=1}^{m+1} R^k(u) + h(u)$ .

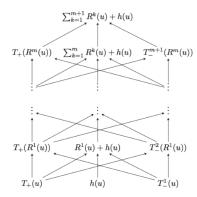

Fig 2. The network  $(T_{+}(u), T_{-}^{1}(u), h(u)) \mapsto \sum_{k=1}^{m+1} R^{k}(u) + h(u)$ .

# Realization of $Mult_m(x, y)$

- Note that all weight parameters' absolute values are bounded by 1 in network  $N_m$ .
- Set  $u = \frac{x-y+1}{2}$ ,  $h(u) = \frac{x+y}{2}$  and apply  $N_m$  to approximate ①. Set  $u = \frac{x+y}{2}$ ,  $h(u) = \frac{1}{4}$  and apply  $N_m$  to approximate ②.
- Concatenate two constructed networks in parallel, then we have a network with m+1 hidden layers and width vector  $(2,6,6,\ldots,6,2)$  that computes:

$$(x,y) \to \left(\underbrace{\sum_{k=1}^{m+1} R^{(k)} \left(\frac{x-y+1}{2}\right) + \frac{x+y}{2}}_{=a}, \underbrace{\sum_{k=1}^{m+1} R^{(k)} \left(\frac{x+y}{2}\right) + \frac{1}{4}\right)}_{=b}$$

Key Ideas

## Realization of $Mult_m(x, y)$

To ensure the final output to be in [0,1], we apply to the a,b the two hidden layer network

$$(a,b) \rightarrow (1-(1-(a-b))_+)_+ = (a-b)_+ \wedge 1.$$

Error bound for approximating xy can be derived as follows:

$$|Mult_{m}(x,y) - xy| \leq \left| \sum_{k=1}^{m+1} R^{(k)} \left( \frac{x-y+1}{2} \right) - g \left( \frac{x-y+1}{2} \right) \right| + \left| \sum_{k=1}^{m+1} R^{(k)} \left( \frac{x+y}{2} \right) - g \left( \frac{x+y}{2} \right) \right| \leq 2^{-m-1} + 2^{-m-1} = 2^{-m}.$$

Second Step

Next goal is to construct a product operator which returns approximately  $\prod_{i=1}^{r} x_i$  for  $\mathbf{x} \in [0,1]^r$ .

Proof

**(Lemma A.3.)** For any positive integer *m*, there exists a network

$$\textit{Mult}_m^r \in \mathcal{F}((m+5)\lceil log_2r \rceil, (r, 6r, 6r, \dots, 6r, 1))$$

such that  $Mult_m^r \in [0, 1]$  and

$$\left| Mult_m^r(X) - \prod_{i=1}^r x_i \right| \le r^2 2^{-m}, \quad \forall \mathbf{x} = (x_1, x_2, \dots, x_r) \in [0, 1]^r.$$

Moreover,  $Mult_m^r(x) = 0$  if one of the components of x is zero.

# Realization of $Mult_m^r(x_1,\ldots,x_r)$

11 For  $q = \lceil log_2r \rceil$ , construct a first hidden layer as follows:

$$(x_1,\ldots,x_r) \to (x_1,\ldots,x_r,\underbrace{1,\ldots,1}_{-2q-r}).$$

- 2 Apply the network  $Mult_m$  in Lemma A.2. to the pairs  $(x_1, x_2), (x_3, x_4), \dots, (1, 1)$  in order to compute  $(Mult_m(x_1, x_2), \dots, Mult_m(1, 1)) \in \mathbb{R}^{2^{q-1}}.$
- Repeat Step 2. until there is only one entry left.
- The resulting network is called  $Mult_m^r$  and has q(m+5) hidden layers and all parameters bounded by one.

Second Step

For q = 1, the bound holds trivially by Lemma A.2. Assume that when q = k - 1, a following bound holds:

$$\left| Mult_m^r(X) - \prod_{i=1}^r x_i \right| \le 3^{k-2} 2^{-m}.$$

We set  $a, b, c, d \in [0, 1]$  as follows:

- a : Output of network 1,  $Mult_m^r(x)$ , when q = k 1.
- b : Output of network 2,  $Mult_m^r(x)$ , when q = k 1.
- c: The true value of product network 1 should have.
- d: The true value of product network 2 should have.

# Error bound on $Mult_m^r(x_1, \ldots, x_r)$

We want to check 
$$|Mult_m(a,b)-cd| \leq 3^{k-1}2^{-m} \leq r^22^{-m}$$
.

$$|Mult_m(a,b) - cd| = |Mult_m(a,b) - ab + ab - cd|$$
 $\leq |Mult_m(a,b) - ab| + |ab - cd|$ 
 $= 2^{-m} + |ab - bc + bc - cd|$ 
 $\leq 2^{-m} + |b| |a - c| + |c| |b - d|$ 
 $\leq 2^{-m} + 3^{k-2}2^{-m} + 3^{k-2}2^{-m}$ 
 $\leq 3^{k-1}2^{-m} \leq r^22^{-m},$ 

where in the last inequality, we use the fact k = q and  $(q - 1) \log(3) < 2(q - 1) < 2 \log_2 r = \log_2 r^2$ .

# Realization of $Mon_{m,\gamma}^r(x_1,\ldots,x_r)$

- Using the network operator  $Mult_m^r$ , we are now ready to construct a network which can approximate all monomials of input data  $x \in [0, 1]^r$  with degree up to  $|\alpha| \le n$ .
- 2 Here we use a multi-index notation and  $C_{r,\gamma}$  denotes total number of monomials with degree up to  $|\alpha| \le n$ .

**(Lemma A.4.)** For  $\gamma > 0$  and any positive integer m, there exists a network

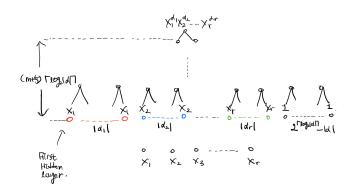

$$Mon_{m,\gamma}^r \in \mathcal{F}(1+(m+5)\lceil \log_2(\gamma \vee 1)\rceil, \ (r,6\lceil \gamma \rceil C_{r,\gamma},\ldots,6\lceil \gamma \rceil C_{r,\gamma},C_{r,\gamma})),$$

such that  $Mon_{m,\gamma}^r \in [0,1]^{C_{r,\gamma}}$  and

$$\left| Mon_{m,\gamma}^{r}(x) - (x^{\alpha})_{|\alpha| < \gamma} \right|_{\infty} \le r^{2}2^{-m}, \quad \forall x \in [0,1]^{r}.$$

# Realization of $Mon_{m}^{r}(x_{1},...,x_{r})$

- Let's say we want to build a network which can approximate following monomial with degree  $|\alpha|: x^{\alpha} = x_1^{\alpha_1} x_2^{\alpha_2} \dots x_r^{\alpha_r}$ .
- A key idea for building such a network is to construct a first hidden layer with  $|\alpha_1| \ x_1 s, \ldots, |\alpha_r| \ x_r s$  and  $2^{\lceil \log_2 |\alpha| \rceil} |\alpha| \ 1s$ .

## Realization of $Hat^r(x_1, \ldots, x_r)$

**(Lemma B.2.)** For any positive integer *M* and *m*, there exists a network

$$Hat^r \in \mathcal{F}(2 + (m+5)\lceil \log_2 r \rceil, (r, 6r(M+1)^r, \dots, 6r(M+1)^r, (M+1)^r), s, 1)$$

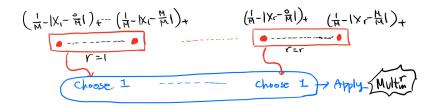

with  $s \le 49r^2(M+1)^r(1+(m+5)\lceil \log_2 r \rceil)$  such that  $Hat^r \in [0,1]^{(M+1)^r}$  and for any  $\mathbf{x}=(x_1,x_2,\ldots,x_r)\in [0,1]^r$ ,

$$\left| Hat^r(x) - \left( \prod_{j=1}^r \left( \frac{1}{M} - |x_j - x_j^{\ell}| \right)_+ \right)_{x_{\ell} \in D(M)} \right|_{\infty} \le r^2 2^{-m}.$$

For any  $x_{\ell} \in D(M)$ , the support of the function  $x \to (Hat^r(x))_{x_{\ell}}$  is moreover contained in the support of the function  $x \to \prod_{i=1}^r (1/M - |x_i - x_i^{\ell}|)_+$ .

Second Step

- Main goal of this Lemma is to construct a neural network which can approximate  $\prod_{j=1}^{r} (1/M |x_j x_j^{\ell}|)_+$  for all the points in the grid (i.e.  $\forall x_{\ell} \in D(M)$ ) with high accuracy.
- First, for each coordinate of  $x_j$ , we need to build a network layer which computes  $(1/M |x_j \ell/M|)_+$  for all  $\ell \in \{0, ..., M\}$ .
- Second, choose one out of M+1 quantities for each coordinate index and apply  $Mult_m^r$  operator for those r chosen values.

## Realization of $Hat^r(x_1, \ldots, x_r)$

First two hidden layers of network  $Hat^r$  can be constructed as follows: Note that

$$(1/M - |x_j - \ell/M|)_+ = (1/M - (x_j - \ell/M)_+ - (\ell/M - x_j)_+)_+$$

First hidden layer has 2r(M+1) nodes and 4r(M+1) non-zero weight parameters. Second hiddn layer has r(M+1) nodes and 3r(M+1) non-zero weight parameters.

# Realization of $Hat^r(x_1, ..., x_r)$

- It remains to apply Mul<sub>m</sub> operator to r chosen values in second hidden layer of Hat<sup>r</sup>.
- 2 As there are  $(M+1)^r$  of these networks,  $Mul_m^r$ , this requires  $6r(M+1)^r$  units in each hidden layer and  $42r^2(M+1)^r((m+5)\lceil \log_2 r \rceil + 1)$  non-zero parameters for the multiplication.
- Note that the total number of non-zero parameters of the network in  $\mathcal{F}(L,(p_1,\ldots,p_L))$  can be bounded by  $\sum_{\ell=0}^L p_\ell p_{\ell+1} + \sum_{\ell=1}^L p_\ell$ .
- 4 Then non-zero parameters of  $Mult_m^r$  can be bounded as follows:

$$6r^{2} + 36r^{2}((m+5)\lceil \log_{2} r \rceil - 1) + 6r + 6r((m+5)\lceil \log_{2} r \rceil)$$

$$= 36r^{2}(m+5)\lceil \log_{2} r \rceil - 30r^{2} + 6r + 6r(m+5)\lceil \log_{2} r \rceil$$

$$\leq 42r^{2}((m+5)\lceil \log_{2} r \rceil + 1).$$

## Realization of $Hat^r(x_1, ..., x_r)$

Combining all the information elaborated above, we can finally construct a network which can approximate  $\prod_{j=1}^{r} (1/M - |x_j - x_j^{\ell}|)_+$  for all  $x_{\ell} \in D(M)$ , whose network architecture is as follows:

$$Hat^r \in \mathcal{F}(2 + (m+5)\lceil \log_2 r \rceil, (r, 6r(M+1)^r, \dots, 6r(M+1)^r, (M+1)^r), s, 1)$$

The number of non-zero parameters s can be controlled trivially as follows:

$$s \le 42r^2(M+1)^r((m+5)\lceil \log_2 r \rceil + 1) + 7r(M+1)$$
  
 
$$\le 49r^2(M+1)^r((m+5)\lceil \log_2 r \rceil + 1)$$

#### Third Step

Preliminaries

Second Step

Now we are ready to construct a neural network,  $\tilde{f}$ , which can approximate Local Taylor Approximated f(x) defined as:

$$\sum_{x_\ell \in D(M)} P_{x_\ell}^\beta f(x) \prod_{j=1}^r \left(1 - M|x_j - x_j^\ell|\right)_+$$

For all points in the grid  $x_{\ell} \in D(M)$ , we know how to construct neural networks which approximate :

$$P_{x_\ell}^{\beta}f(x)$$
 and  $\prod_{j=1}^r \left(1/M - |x_j - x_j^{\ell}|\right)_+,$ 

through  $\mathit{Mon}^r_{m,\gamma}$  and  $\mathit{Hat}^r$ , respectively. However, in order to realize an inner-product of outputs from these two networks through a fully-connected neural network with ReLU activation function, we need one more trick.

Imagine we have a neural network,  $\Phi_1 \in [-1,1]$ , which can approximate  $\sin(x)$  function and another neural network,  $\Phi_2 \in [-1,1]$ , which approximates  $\cos(x)$  function. We want to have a neural network approximating  $\sin(x) + \cos(x)$  through  $\Phi_1$  and  $\Phi_2$ . For the construction of network, we apply ReLU activation function. We need to construct a network in a following way :

$$6^{\text{Rell}}(\underline{\mathbb{F}}_{1}(x)+1)+6^{\text{kell}}(\underline{\mathbb{F}}_{2}(x)+1)-2$$
: output layer bell  $(\underline{\mathbb{F}}_{2}(x)+1)$ 

Preliminaries

Third Step

By using the aforementioned idea, we need to scale and shift  $P_{x_{\ell}}^{\beta}f(x)$  so that the modified value is in [0, 1]. In order to do this, we first need to obtain the maximum of  $P_{x_{\ell}}^{\beta}f(x)$ . Recall  $P_{x_{\ell}}^{\beta}f(x)$  is defined as:

$$P_{x_{\ell}}^{\beta}f(x) := \sum_{\alpha: |\alpha| \leq n} (\partial^{\alpha}f)(x_{\ell}) \frac{(x-x_{\ell})^{\alpha}}{\alpha!}$$

By *r*-dimensional binomial theorem, we can rewrite  $(x - x_{\ell})^{\alpha}$  as

$$(x-x_\ell)^{\alpha} = \sum_{\gamma \leq \alpha} {\alpha \choose \gamma} (-x_\ell)^{\alpha-\gamma} x^{\gamma}, \quad \forall x \in [0,1]^r, \alpha \in \mathbb{N}_0^r.$$

Here for vectors  $\gamma, \alpha \in \mathbb{N}_0^r$ ,  $\gamma \leq \alpha$  means that

$$\gamma_1 \leq \alpha_1, \ldots, \gamma_r \leq \alpha_r$$
.

#### Bound on $P_{x_0}^{\beta}f(x)$

Then we can write  $P_{x_{\ell}}^{\beta} f(x)$  as follows:

$$P_{x_{\ell}}^{\beta}f(x) = \sum_{\alpha: |\alpha| \le n} \frac{(\partial^{\alpha}f)(x_{\ell})}{\alpha!} \sum_{\gamma \le \alpha} {\alpha \choose \gamma} (-x_{\ell})^{\alpha-\gamma} x^{\gamma}$$

$$= \sum_{\gamma: |\gamma| \le n} \left[ \sum_{\gamma \le \alpha \& |\alpha| \le n} \frac{(\partial^{\alpha}f)(x_{\ell})}{\alpha!} {\alpha \choose \gamma} (-x_{\ell})^{\alpha-\gamma} \right] x^{\gamma}.$$

$$= C_{\gamma}$$

The absolute value of  $C_{\gamma}$  can be controlled by using facts  $x_{\ell} \in [0, 1]^r$ ,  $f \in \mathcal{C}^{\beta}_{r}([0,1]^{r},K)$  and  $(\alpha-\gamma)! \geq 1$ : For fixed  $\gamma \in \mathbb{N}^{r}_{0}$ 

$$|C_{\gamma}| \leq \sum_{\gamma \leq \alpha , k |\alpha| \leq n} \frac{|(\partial^{\alpha} f)(x_{\ell})|}{(\alpha - \gamma)! \gamma!} |(-x_{\ell})^{\alpha - \gamma}| \leq \frac{K}{\gamma!}.$$

Here, we omit the dependency of  $x_{\ell}$  when writing  $C_{\gamma}$  for simplicity.

# Bound on $P_{x_{\ell}}^{\beta}f(x)$

Preliminaries

Third Step

Finally, we can bound  $P_{x_{\sigma}}^{\beta}f(x), \forall x \in [0, 1]^r$  as follows:

$$egin{align} P^eta_{x_\ell} f(x) &= \sum_{\gamma: |\gamma| \leq n} C_\gamma x^\gamma \leq \sum_{\gamma: |\gamma| \leq n} |C_\gamma| \ &\leq \sum_{\gamma \geq 0} |C_\gamma| \leq \sum_{\gamma \geq 0} rac{K}{\gamma!} \ &= K \prod_{j=1}^r \sum_{\gamma_j > 0} rac{1}{\gamma_j !} = K e^r. \end{split}$$

Preliminaries

Third Step

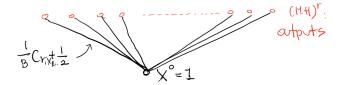

Let  $B = \lceil 2Ke^r \rceil$ . Then we are ready to construct a network,  $Q_1$ , which can approximate  $\frac{P_{\chi_{\ell}}^{\beta}f(x)}{R} + \frac{1}{2} \in [0,1]^{(M+1)'}$ . We can simply add one hidden layer to the network  $Mon_{m\beta}^r$  as follows :

Note that all the absolute values of weight and bias parameters used for output layer are bounded by 1, since  $\frac{1}{B}|C_{\gamma,x_{\ell}}| \leq 1$  for all  $\gamma: |\gamma| \leq n$ ,  $x_{\ell} \in D(M)$ . We use  $L^* := (m+5)\lceil \log_2(\bar{\beta} \vee r) \rceil$ .

Preliminaries

Third Step

Note that  $\frac{1}{2}$  can be added by putting  $\frac{1}{R}C_{\gamma,X_{\ell}} + \frac{1}{2}$  weight on monomial  $x^0 = 1$  for each  $\gamma : |\gamma| \le n$  and  $x_\ell \in D(M)$ .

Through these constructions, it is obvious that  $Q_1$  has a following network structure:

$$\textit{Q}_1 \in \mathcal{F}\big(2 + \textit{L}^*, (\textit{r}, 6\lceil \beta \rceil \textit{C}_{\textit{r},\beta}, \ldots, 6\lceil \beta \rceil \textit{C}_{\textit{r},\beta}, \textit{C}_{\textit{r},\beta}, (\textit{M}+1)^{\textit{r}})\big),$$

such that  $Q_1 \in [0, 1]^{(M+1)'}$ .

Preliminaries

Third Step

The approximation error in a  $L^{\infty}$  sense of the network  $Q_1$  for any  $x \in [0, 1]^r$  can be calculated trivially as : For any integer  $m \ge 1$ ,

$$\begin{split} \left|Q_1(x) - \left(\frac{P_{x_\ell}^\beta f(x)}{B} + \frac{1}{2}\right)_{x_\ell \in D(M)}\right|_\infty &\leq \frac{1}{B} \sum_{\gamma: |\gamma| \leq n} |C_\gamma| \beta^2 2^{-m} \\ &\leq \frac{Ke^r}{B} \beta^2 2^{-m} \leq \beta^2 2^{-m}. \end{split}$$

Total number of non-zero parameters can be bounded as :

$$6r(\beta+1)C_{r,\beta}+42(\beta+1)^2C_{r,\beta}^2(1+L^*)+C_{r,\beta}(M+1)^r$$
.

Preliminaries

Third Step

Consider now a parallel network ( $Q_1$ ,  $Hat^r$ ):

- Observe that  $C_{r,\beta} \le (\beta+1)^r \le N$  by the definition of  $C_{r,\beta}$  and the assumptions on N in the statement of Theorem 5.
- **2** The parallelized network  $(Q_1, Hat^r)$  has a following architecture:

$$(Q_1, Hat^r) \in \mathcal{F}(2 + (m+5)\lceil \log_2(r \vee \beta) \rceil,$$
$$(r, 6(r + \lceil \beta \rceil)N, \dots, 6(r + \lceil \beta \rceil)N, 2(M+1)^r))$$

3 Note that all network parameters are bounded by 1.

The total number of network parameter of  $(Q_1, Hat^r)$  can be bounded as follows: We set M to be the largest integer such that  $(M+1)^r \le N$ .

$$\begin{aligned} &6r(\beta+1)C_{r,\beta}+42(\beta+1)^{2}C_{r,\beta}^{2}(L^{*}+1)+C_{r,\beta}(M+1)^{r}+49r^{2}(M+1)^{r}(L^{*}$$

where in the last inequality, we use the fact:

 $< 98(\beta + r + 1)^{3+r}N(m+5)$ 

$$1 + (m+5)\lceil \log_2(\beta \vee r) \rceil \le (m+5)(1+\lceil \log_2(\beta \vee r) \rceil)$$
  
$$\le 2(m+5)(\beta \vee r)$$
  
$$\le 2(m+5)(\beta+r+1).$$

Proof

#### Third Step: Substep 3.

- Next, we pair the  $x_{\ell}$ th entry of  $Q_1$  and  $Hat^r$  and apply to each of the  $(M+1)^r$  pairs the  $Mult_m$  network described in Lemma.A.2.
- In the last layer, we add up all entries.
- $\blacksquare$  Finally, we have a network  $Q_2$  which can approximate

$$\sum_{x_{\ell} \in D(M)} \left( \frac{P_{x_{\ell}}^{\beta} f(x)}{B} + \frac{1}{2} \right) \prod_{j=1}^{r} \left( \frac{1}{M} - |x_{j} - x_{j}^{\ell}| \right)_{+}.$$

The network's architecture is as follows:

$$Q_2 \in \mathcal{F}(3 + (m+5)(1 + \lceil \log_2(r \vee \beta) \rceil),$$
$$(r, 6(r + \lceil \beta \rceil)N, \dots, 6(r + \lceil \beta \rceil)N, 1)).$$

Preliminaries

Third Step

Note that the required number of parameters for  $Mult_m$  is at most :

$$6+12+36(m+3)+6(m+4) \leq 42(m+5)$$

Proof

We need  $(M+1)^r$  Mult<sub>m</sub>s serially and  $(M+1)^r$  parameters for adding up entries in the last hidden layer. This means that at least

$$42(m+5)(M+1)^r + (M+1)^r \le 43(m+5)N$$

non-zero parameters are required for the steps 1. and 2. in the previous slide. By combining the bound we obtained for the number of non-zero parameters for  $(Q_1, Hat^r)$  network, the s for  $Q_2$  is bounded by :

$$141(r+\beta+1)^{3+r}N(m+5)$$
.

# By triangular inequality, we can get the approximation error bound for $Q_2$ :

$$\begin{vmatrix} Q_2 - \sum_{x_{\ell} \in D(M)} \left( \frac{P_{x_{\ell}}^{\beta} f(x)}{B} + \frac{1}{2} \right) \prod_{j=1}^{r} \left( \frac{1}{M} - |x_j - x_j^{\ell}| \right)_{+} \end{vmatrix}$$

$$\leq \sum_{x_{\ell} \in D(M): ||x - x_{\ell}||_{\infty} \leq 1/M} (1 + r^2 + \beta^2) 2^{-m}$$

$$\leq (1 + r^2 + \beta^2) 2^{r-m}.$$

In the last inequality, we use the fact for any  $x \in [0,1]^r$ , there are  $2^r$  points in the grid D(M) whose  $L^{\infty}$  distance between an input data x is within 1/M.

Finally, we need a network operator which can perform re-scaling and re-shifting as follows:

$$\sum_{x_{\ell} \in D(M)} \left( \frac{P_{x_{\ell}}^{\beta} f(x)}{B} + \frac{1}{2} \right) \prod_{j=1}^{r} \left( \frac{1}{M} - |x_{j} - x_{j}^{\ell}| \right)_{+}$$

$$\rightarrow \sum_{x_{\ell} \in D(M)} P_{x_{\ell}}^{\beta} f(x) \prod_{j=1}^{r} \left( 1 - M|x_{j} - x_{j}^{\ell}| \right)_{+}$$

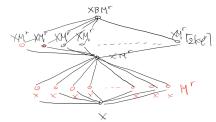

Note that

$$\sum_{x_{\ell} \in D(M)} \left( \frac{P_{x_{\ell}}^{\beta} f(x)}{B} + \frac{1}{2} \right) \prod_{j=1}^{r} \left( \frac{1}{M} - |x_{j} - x_{j}^{\ell}| \right)_{+}$$

$$= \underbrace{\frac{1}{BM^{r}} \sum_{x_{\ell} \in D(M)} P_{x_{\ell}}^{\beta} f(x) \prod_{j=1}^{r} \left( 1 - M|x_{j} - x_{j}^{\ell}| \right)_{+} + \frac{1}{2M^{r}}}_{:=a}.$$

We need a network operator with ReLU activation function computing  $a \rightarrow BM^r(a-1/2M^r)$ .

The network  $x \to BM^r x$  is in the class  $\mathcal{F}(3, (1, M^r, 1, B, 1))$  with shift vectors  $v_j$  are all equal to zero and weight matrices  $W_j$  having all entries equal to one.

Network  $a oup BM^r(a-1/2M^r)$  computes in the first hidden layer  $(a-1/2M^r)_+$  and  $(1/2M^r-a)_+$  and then applies the network  $x oup BM^r x$  to both units. In the output layer the second value is subtracted from the first one.

It is trivial to check network  $a \to BM^r(a-1/2M^r)$  has at most 12N+6 non-zero parameters.

- For the network  $x \to BM^r x$ , we need  $2M^r + 2\lceil 2Ke^r \rceil$  parameters. Because of the assumption  $N \ge (K+1)e^r$ , at most 6N parameters are required.
- 2 We need two  $x \to BM^r x$  networks and extra 6 parameters for the network  $a \to BM^r (a 1/2M^r)$ .

Apply the network  $a \to BM^r(a-1/2M^r)$  to the output of  $Q_2$ , then there exists a network  $Q_3$  in

$$Q_3 \in \mathcal{F}(8 + (m+5)(1 + \lceil \log_2(r \vee \beta) \rceil),$$
$$(r, 6(r + \lceil \beta \rceil)N, \dots, 6(r + \lceil \beta \rceil)N, 1)),$$

such that, for all  $x \in [0, 1]^r$ ,

$$\begin{split} & \left| Q_3 - \sum_{x_{\ell} \in D(M)} P_{x_{\ell}}^{\beta} f(x) \prod_{j=1}^{r} \left( 1 - M |x_j - x_j^{\ell}| \right)_{+} \right| \\ & \leq \lceil 2Ke^r \rceil M^r (1 + r^2 + \beta^2) 2^{r-m} \\ & \leq (2K + 1)(2e)^r M^r (1 + r^2 + \beta^2) 2^{-m} \\ & \leq (2K + 1)(1 + r^2 + \beta^2) 6^r N 2^{-m}. \end{split}$$

Preliminaries

Third Step

The number of non-zero parameters of  $Q_3$  is bounded by

$$141(r+\beta+1)^{3+r}N(m+5)+(12N+6)\leq 141(r+\beta+1)^{3+r}N(m+6).$$

We are ready to obtain an approximation error bound:

$$\begin{split} \left\| \tilde{f} - f \right\|_{L^{\infty}[0,1]^r} &\leq \left\| P^{\beta} f(X) - f(X) \right\|_{L^{\infty}[0,1]^r} + \left\| \tilde{f} - P^{\beta} f(X) \right\|_{L^{\infty}[0,1]^r} \\ &\leq K M^{-\beta} + (2K+1)(1+r^2+\beta^2)6^r N 2^{-m} \\ &\leq 3^{\beta} N^{-\frac{\beta}{r}} + (2K+1)(1+r^2+\beta^2)6^r N 2^{-m}. \end{split}$$

where in the last inequality, we use

$$(M+1)^r \le N \le (M+2)^r \le (3M)^r$$
.

We finally conclude the proof.
